01 BACKGROUND

PROBLEM & TERMINOLOGY & OBJECTIVES

About the e-voting

1 Definition

E-voting is the use of electronic devices, such as voting machines or a web browser, to cast votes.

2 Major Terminologies

In addition, ideal e-voting systems have **ballot-privacy, individual-verifiability** which is better than existing voting system.

Terminologies

PRIVACY

Ballot-privacy (BP)

No outside observer can determine for whom a voter voted.

Coercion-resistance (CR)

A voter cannot interact with a coercer during the election to prove how she is voting.

VERIFIABILITY

Individual verifiability (IV)

A voter can verify that the ballot containing his vote is in the published set of “all” (as claimed by the system) votes.

Universal verifiability (UV)

Anyone can verify that the result corresponds with the published set of “all” votes.

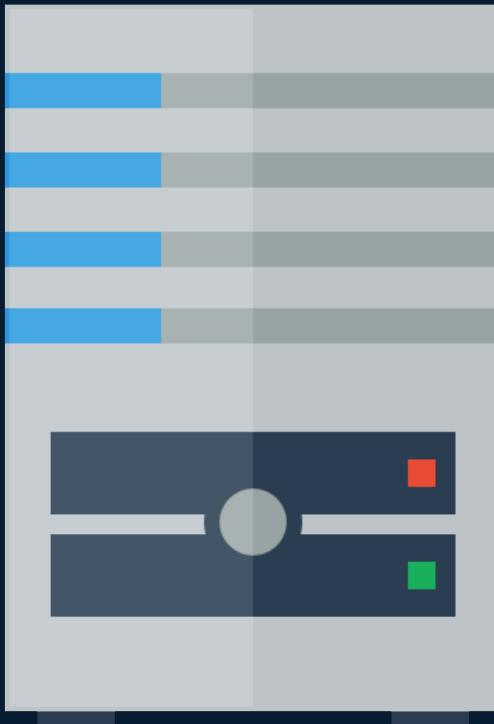

■ Terminologies

What if...

Voter A

`mxLqfJvTTEojWVZVTanEcXs1kXaBkdoqfX`

(Voter address is anonymity for all)

0.305 BTC

Refers(OP_RETURN):
Candidate Name

Election Authority

`n4Kc1AwFos3aZRvD3Tc9imzeMeA8E9DEUr`

(Make this address public to all voters)

About the blockchain

“

IS IT PERFECT NOW?

”

“ NOT YET

The **attacker** who wants to
modify the voting result
can use his own bitcoin address to
vote twice or more.

Ring Signature

Sign a message:

$$\sigma(m, Sk_i, Pk_1, Pk_2 \dots Pk_n)$$

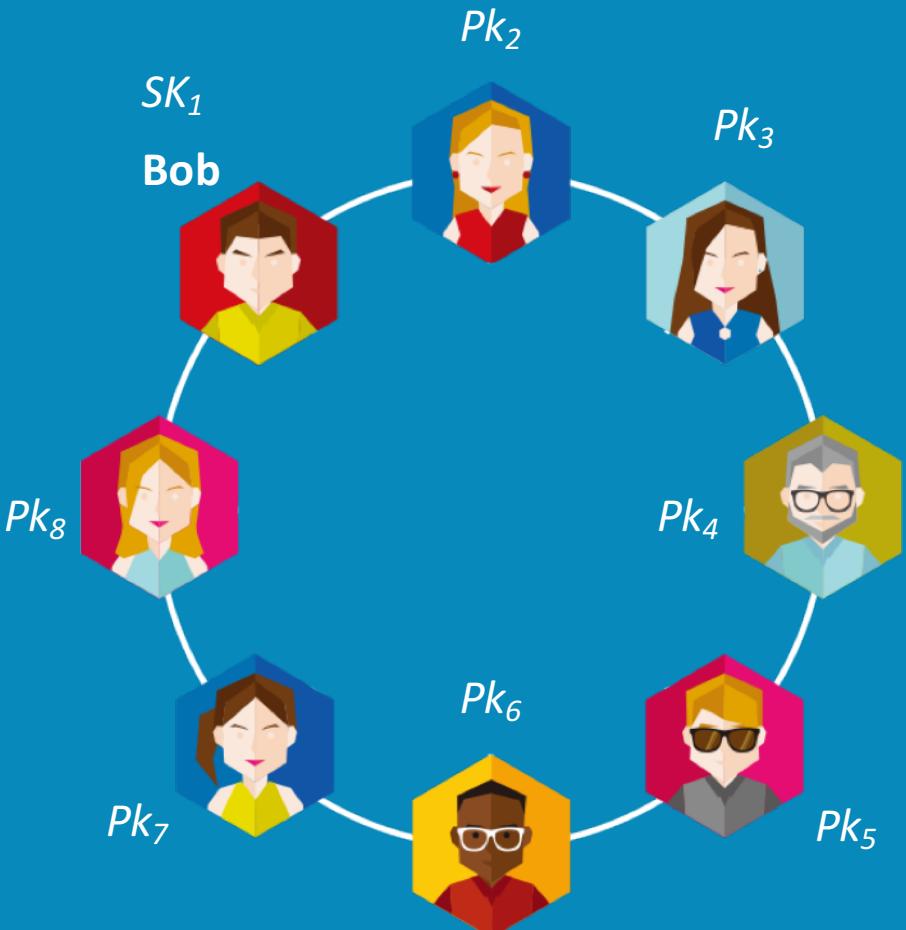

Verify a signature:

$$\text{verify}(m, \sigma, Pk_1, Pk_2 \dots Pk_n)$$

What if make the OP_RETURN like this?

$$\text{commitment}(\sigma, \text{Candidate Name})$$

m Message to sign
 Sk_i Private key of member i
 Pk_i Public key of member i

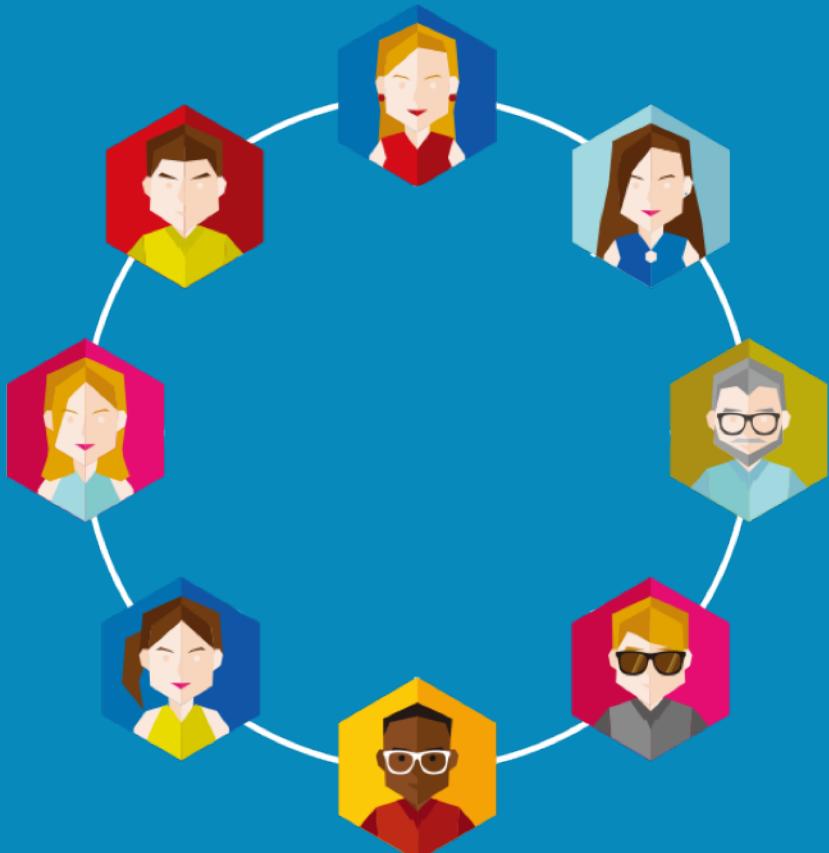

“

WHY RING SIGNATURE

”

Compared to group signature

- ✓ No administrator
- ✓ Free Structure, every member is equal
- ✓ Everyone is anonymous

■ Summary

E-voting

A real e-voting system for Registration Authority, Election Authority, Voters, Candidates

Blockchain

The public ledger to store the information of signatures and candidate id. It protect the privacy of voters

Ring Signature

A signature algorithm to sign the candidate id to ensure the verifiability of individual and universal

BlockVotes

An e-voting system based on blockchain and ring signatures. The network of blockchain can choose the bitcoin and the testnet

02 PROTOCOL

AN E-VOTING SCHEME

Definition and Assumption

Voter (V_i)

The voters should be a set of list.
For each voter to vote can be
defined as V_i .
The voter should transfer his public
key(PK_i) to EA .

Candidate(C_i)

The candidates should be a set of list.
For each candidate to vote can be
defined as C_i

Registration Authority

The voter(V_i) should register in RA
to get ready to vote.
The candidate(C_i) should register in
RA with his information and the RA
will give him the id of candidate.

Election Authority

The EA is responsible for creating a
vote, limiting the voter numbers of the
voting, paying the voting fees for the
bitcoin address(A_i) generated
automatically in the backend.
The EA has its own bitcoin address(A_E).

Assumption: Registration Authority and Election Authority will not correspond.

Protocol - Preparation Stage

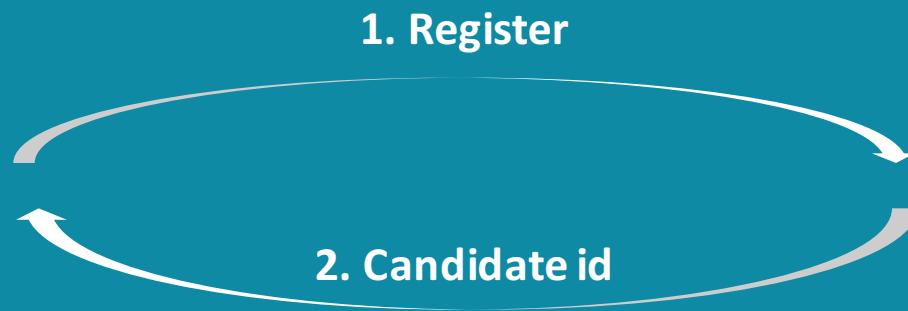

Election Authority

1. The EA save his own private key(A_E) of the bitcoin into the system.
2. The EA create a new voting item with the voting id(L_i), title, limitation of the voting numbers(n) and the description of this voting item.
3. The system will generate the numbers of the n bitcoin addresses(A) as the addresses pool automatically.

Protocol - Registration Stage

Candidate (C_i)

Registration Authority

1. The candidate takes his passport and goes to the *RA* in real life.
2. The RA verifies his identity and ask his name, his description and save it into system.
3. The RA will give him his candidate id(C_i).

Protocol - Registration Stage

Voter (V_i)

Registration Authority

1. The voter(V_i) takes his passport and goes to the RA in real life.
2. The RA verifies his identity and ask the email address of the voter, sending him an email with registration code link as LK_i to avoid multiple registration.
3. The LK_i is generated random and has no relationship with the voters name and email address.

Protocol - Registration Stage

Voter (V_i)

3. Open the link from the email

4. Generate keys and saves pub key

Registration Authority

1. The voter opens the registration links LK_i .
2. The voter V_i generate his key pair (SK_i, PK_i).
3. The voter V_i save his public key PK_i into the system.
4. At the end of the registration, the set of voters should be fixed as a number of n.
5. The hash value of each public key ($\text{hash}(PK), PK$) should storage as a set Set into the system.

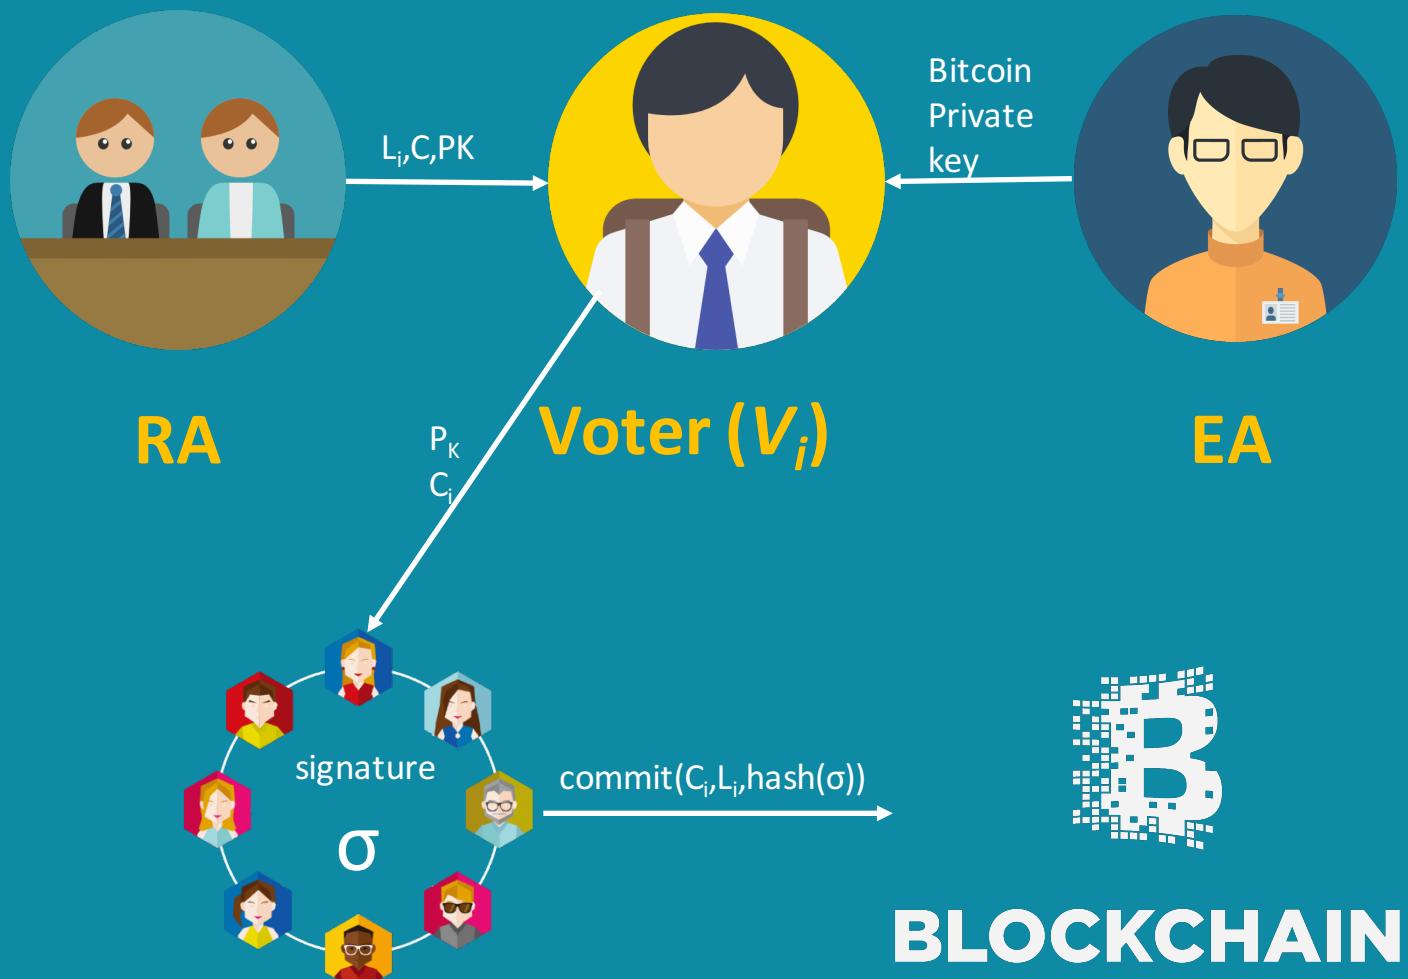

Protocol - Publish Stage

Election Authority

1. The EA start the voting .
2. EA creates k BTC in his own bitcoin.
3. EA pays a fixed amount of bitcoin k to each A_i for the voting costs with an OP_RETURN including the $\text{hash}(PK_i)$.

Protocol - Vote Stage

1. The voter chooses the candidate C_i he vote for and the current voting id L_i .
2. The RA returns the public keys set PK to the voter.
3. The voter use his private key SK_i and all public keys PK to sign the signature of the candidate C_i as $\sigma(C_i, SK_i, PK)$. The system saves the set of $(\sigma, \text{hash}(\sigma))$ at the same time.
4. The voter select a bitcoin address A_i to publish from the bitcoin address pool and EA returns the private key of the address to voter.
5. The voter V_i pays all A_i 's balance the to EA's address with an OP_RETURN of the commitment($\text{hash}(\sigma(C_i, SK_i, PK)), C_i, L_i$).

Protocol – Tally Stage

BLOCKCHAIN

Anyone

1. The system will return all sets of $(\sigma, \text{hash}(\sigma))$ and all public keys PK automatically.
2. The system will fetch all transactions in EA's bitcoin address automatically.
3. The system will fetch the OP_RETURN code from each transaction and verify the signature validity.
4. The system will count each valid transaction and add 1 to the candidate C_i .
5. If the voter A_i is absent, count it as the abstain from voting.
6. If bitcoin transaction history has more than twice transactions from the same A_i , count the first and ignore others.

Protocol – Verify Stage

Voter (V_i)

BLOCKCHAIN

1. The system will return all public keys PK automatically.
2. For each voter V_i , he can use a set of all public keys PK , the ring signature σ , the candidate C_i to verify his vote.
3. The voter V_i can use the transaction id to fetch the commitment from the blockchain to verify if the signature is published in the right way.

03 BlockVotes

IMPLEMENTATION & TECHNOLOGY STACK
& TOOLS

Technology Stack

BIG PROJECT

- ✓ Login and logout
- ✓ User role control
- ✓ Public APIs to list bitcoin address, public keys and etc..
- ✓ Generate the bitcoin address into WIF format
- ✓ Sending the emails
- ✓ Switch the network of blockchain
- ✓ Create a bitcoin transaction into hex format
- ✓ Publish the voting result to blockchain
- ✓ Use ring signature algorithm to sign voting result
- ✓ Tally the votes in real time
- ✓ Verify the votes in real time
- ✓

The screenshot shows a PHP development environment with the following details:

- Project Structure:** The project is named "blockvotes" and is located at "/Applications/XAMPP". It contains an "app" folder which further contains "Auth", "Controllers", "EA", "RA", and "Voter" subfolders. Each of these subfolders contains several PHP files (e.g., Auth.php, AuthController.php, PasswordController.php, etc.).
- HomeController.php (highlighted):** This file is highlighted in blue in the code editor. It contains the following code:

```
<?php  
use ...  
  
/**  
 * Public Page  
 */  
$app->get( pattern: '/', callable: 'HomeController.php')  
  
// Public API  
$app->get( pattern: '/api/bitcoinaddress', callable: 'CandidateController.php')  
$app->get( pattern: '/api/publickey', callable: 'CandidateController.php')  
$app->get( pattern: '/api/getcandidates', callable: 'CandidateController.php')  
$app->get( pattern: '/api/sighash', callable: 'CandidateController.php')  
  
$app->post( pattern: '/api/sigpairs', callable: 'CandidateController.php')  
  
$app->get( pattern: '/vote/fail', callable: 'VoterController.php')  
$app->get( pattern: '/verify/home', callable: 'VoterController.php')  
$app->get( pattern: '/verify/now', callable: 'VoterController.php')  
$app->get( pattern: '/tally/home', callable: 'VoterController.php')  
$app->get( pattern: '/tally/now', callable: 'VoterController.php')  
  
/**  
 * Public page for voters  
 */  
$app->group( pattern: '', function () {  
    $this->get('/vote/start', 'VoterController.php')  
    $this->get('/vote/home', 'VoterController.php')  
    $this->get('/vote/wait', 'VoterController.php')  
    $this->get('/vote/fill', 'VoterController.php')  
    $this->get('/vote/lost', 'VoterController.php')  
    $this->get('/voter/vote', 'VoterController.php')  
    $this->get('/vote/page', 'VoterController.php')  
})  
  
//API  
$this->get('/api/postpubkey', 'PublicAPIController.php')  
$this->get('/api/bitcoinkey', 'PublicAPIController.php')  
});>>> add(new VoterMiddleware($container))
```

Contributor

Thank you for providing this awesome bitcoin library for PHP.
Unfortunately, I've occurred the WIF format bug when using testnet network.
This is due to the getWif(\$compressed) method doesn't judge the network.
I fixed this bug directly and it works now.

Here are what I've done.
Cheers!
